add.edges

Add Edges to a Network Object

Description

Add one or more edges to an existing network object.

Usage

add.edge(x, tail, head, names.eval=NULL, vals.eval=NULL,  
         edge.check=FALSE, ...)
add.edges(x, tail, head, names.eval=NULL, vals.eval=NULL,  
          ...)

Arguments

x an object of class network

tail for add.edge, a vector of vertex IDs reflecting the tail set for the edge to be added;  
     for add.edges, a list of such vectors

head for add.edge, a vector of vertex IDs reflecting the head set for the edge to be added;  
      for add.edges, a list of such vectors

names.eval for add.edge, an optional list of names for edge attributes; for add.edges,  
            a list of such lists

vals.eval for add.edge, an optional list of edge attribute values (matching names.eval);  
           for add.edges, a list of such lists

edge.check logical; should we perform (computationally expensive) tests to check for the  
      legality of submitted edges?

... additional arguments
add.vertices

Details

The edge checking procedure is very slow, but should always be employed when debugging; without it, one cannot guarantee that the network state is consistent with network level variables (see network.indicators).

Edges can also be added/removed via the extraction/replacement operators. See the associated man page for details.

Value

Invisibly, add.edge and add.edges return pointers to their modified arguments; both functions modify their arguments in place.

#Add an edge
add.edge(g,1,2)
g

#Can also add edges using the extraction/replacement operators

#network

add.vertices Add Vertices to an Existing Network

Description

add.vertices adds a specified number of vertices to an existing network; if desired, attributes for the new vertices may be specified as well.

Usage

add.vertices(x, nv, vattr = NULL)
Arguments

- `x` an object of class `network`
- `nv` the number of vertices to add
- `vattr` optionally, a list of attributes with one entry per new vertex

Details

Note that the attribute format used here is based on the internal (vertex-wise) storage method, as opposed to the attribute-wise format used by `network`.

Value

Invisibly, a pointer to the updated `network` object; `add.vertices` modifies its argument in place.

Author(s)

Carter T. Butts ⟨buttsc@uci.edu⟩

References

See Also

`network`, `get.vertex.attribute`, `set.vertex.attribute`

Examples

```r
# Initialize a network object
g <- network.initialize(5)
g

# Add five more vertices
add.vertices(g, 5)
g
```
as.matrix.network

Usage

as.matrix.network(x, matrix.type = NULL, attrname = NULL)
as.matrix.network.adjacency(x, attrname=NULL)
as.matrix.network.edgelist(x, attrname=NULL)
as.matrix.network.incidence(x, attrname=NULL)

Arguments

x                   an object of class network
matrix.type         one of "adjacency","incidence","edgelist", or NULL
attrname            optionally, the name of an edge attribute to use for edge values

Details

If no matrix type is specified, \texttt{which.matrix.type} will be used to make an educated guess based on the shape of \texttt{x}. Where edge values are not specified, a dichotomous matrix will be assumed.

Note that adjacency matrices may also be obtained using the extraction operator. See the relevant man page for details.

Value

An adjacency, incidence, or edgelist matrix

Author(s)

Carter T. Butts (buttsc@uci.edu) and David Hunter (dhunter@stat.psu.edu)

References

\texttt{which.matrix.type, network, network.extraction}

Examples

#Create a random network
m <- matrix(rbinom(25,1,0.5),5,5)
diag(m) <- 0
g <- network(m)

#Coerce to matrix form
as.matrix.network(g,matrix.type="adjacency")
as.matrix.network(g,matrix.type="incidence")
as.matrix.network(g,matrix.type="edgelist")
# Can also use the extraction operator
g[,] # Get entire adjacency matrix
g[1:5,6:10] # Obtain a submatrix

as.network.matrix  Coercion from Matrices to Network Objects

Description

as.network.matrix attempts to coerce its first argument to an object of class network.

Usage

as.network.default(x, ...)
as.network.matrix(x, matrix.type = NULL, directed = TRUE,
  hyper = FALSE, loops = FALSE, multiple = FALSE, bipartite = FALSE,
  ignore.eval = TRUE, names.eval = NULL, na.rm = FALSE,
  edge.check = FALSE, ...)

Arguments

x               a matrix containing an adjacency structure
matrix.type     one of "adjacency", "edgelist", "incidence", or NULL
directed        logical; should edges be interpreted as directed?
hyper           logical; are hyperedges allowed?
loops           logical; should loops be allowed?
multiple        logical; are multiplex edges allowed?
bipartite       count; should the network be interpreted as bipartite? If present (i.e., non-
                NULL) it is the count of the number of actors in the bipartite network. In this
                case, the number of nodes is equal to the number of actors plus the number of
                events (with all actors preceding all events). The edges are then interpreted as
                nondirected.
ignore.eval     logical; ignore edge values?
names.eval      optionally, the name of the attribute in which edge values should be stored
na.rm           logical; ignore missing entries when constructing the network?
edge.check      logical; perform consistency checks on new edges?
...             additional arguments

Details

Depending on matrix.type, one of three edgeset constructor methods will be employed to read
the input matrix (see edgeset.constructors). If matrix.type==NULL, which.matrix.type
will be used to guess the appropriate matrix type.
as.sociomatrix

Value

An object of class network

Author(s)

Carter T. Butts \{buttsc@uci.edu\} and David Hunter \{dhunter@stat.psu.edu\}

diag(m)<-0

# Coerce to network form
g<-as.network.matrix(m,matrix.type="adjacency")

---

as.sociomatrix  

Coerce One or More Networks to Sociomatrix Form

Description

as.sociomatrix takes adjacency matrices, adjacency arrays, network objects, or lists thereof, and returns one or more sociomatrices (adjacency matrices) as appropriate. This routine provides a useful input-agnostic front-end to functions which process adjacency matrices.

Usage

as.sociomatrix(x, attrname = NULL, simplify = TRUE)

Arguments

x  
an adjacency matrix, array, network object, or list thereof.

attrname  
optionally, the name of a network attribute to use for extracting edge values (if x is a network object).

simplify  
logical; should as.sociomatrix attempt to combine its inputs into an adjacency array (TRUE), or return them as separate list elements (FALSE)?
Details

as.sociomatrix provides a more general means of coercing input into adjacency matrix form than as.matrix.network. In particular, as.sociomatrix will attempt to coerce all input networks into the appropriate form, and return the resulting matrices in a regularized manner. If simplify==TRUE, as.sociomatrix attempts to return the matrices as a single adjacency array. If the input networks are of variable size, or if simplify==FALSE, the networks in question are returned as a list of matrices. In any event, a single input network is always returned as a lone matrix.

If attrname is given, the specified edge attribute is used to extract edge values from any network objects contained in x. Note that the same attribute will be used for all networks; if no attribute is specified, the standard dichotomous default will be used instead.

Value

One or more adjacency matrices. If all matrices are of the same dimension and simplify==TRUE, the matrices are joined into a single array; otherwise, the return value is a list of single adjacency matrices.

as.matrix.network, network

Examples

#Generate an adjacency array
g<-array(rbinom(100,1,0.5),dim=c(4,5,5))

#Generate a network object
net<-network(matrix(rbinom(36,1,0.5),6,6))

#Coerce to adjacency matrix form using as.sociomatrix
as.sociomatrix(g,simplify=TRUE)  #Returns as-is
as.sociomatrix(g,simplify=FALSE) #Returns as list
as.sociomatrix(net)             #Coerces to matrix
as.sociomatrix(list(net,g))     #Returns as list of matrices
Description

These methods get, set, list, and delete attributes at the network, edge, and vertex level.

Usage

```r
delete.edge.attribute(x, attrname)
delete.network.attribute(x, attrname)
delete.vertex.attribute(x, attrname)

get.edge.attribute(el, attrname, unlist = TRUE)
get.edge.value(x, attrname, unlist = TRUE)
get.network.attribute(x, attrname, unlist = FALSE)
get.vertex.attribute(x, attrname, na.omit = FALSE, null.na = TRUE,
  unlist = TRUE)
network.vertex.names(x)

list.network.attributes(x)
list.edge.attributes(x)
list.vertex.attributes(x)

set.edge.attribute(x, attrname, value, e=1:length(x$mel))
set.edge.value(x, attrname, value, e=1:length(x$mel))
set.network.attribute(x, attrname, value)
set.vertex.attribute(x, attrname, value, v=1:network.size(x))
```

Arguments

- `el` a list of edges (possibly `network$mel`).
- `x` an object of class `network`.
- `attrname` the name of the attribute to get or set.
- `unlist` logical; should retrieved attributes be `unlisted` prior to being returned?
- `na.omit` logical; should values from missing vertices/edges be removed?
- `null.na` logical; should NULL values be replaced with NAs?
- `value` values of the attribute to be set; these should be in `vector` or `list` form for the edge and vertex cases, or `matrix` form for `set.edge.value`.
- `e` IDs for the edges whose attributes are to be altered.
- `v` IDs for the vertices whose attributes are to be altered.
attribute.methods

Details

The `list.attributes` functions return the names of all edge, network, or vertex attributes (respectively) in the network. All attributes need not be defined for all elements; the union of all extant attributes for the respective element type is returned.

The `get.attribute` functions look for an edge, network, or vertex attribute (respectively) with the name `attrname`, returning its values. Note that, to retrieve an edge attribute from all edges within a network `x`, `x$mel` should be used as the first argument to `get.edge.attribute`; `get.edge.value` is a convenience function which does this automatically. `network.vertex.names` is a convenience function to extract the "vertex.names" attribute from all vertices.

The `set.attribute` functions allow one to set the values of edge, network, or vertex attributes. `set.edge.value` is a convenience function which allows edge attributes to be given in adjacency matrix form. The `delete.attribute` functions, by contrast, remove the named attribute from the network, from all edges, or from all vertices (as appropriate). If `attrname` is a vector of attribute names, each will be removed in turn. These functions modify their arguments in place, although a pointer to the modified object is also (invisibly) returned.

Note that some attribute assignment/extraction can be performed through the various extraction/replacement operators. See the associated man page for details.

Value

For the `list.attributes` methods, a vector containing attribute names. For the `get.attribute` methods, a list containing the values of the attribute in question (or simply the value itself, for `get.network.attribute`). For the `set.attribute` and `delete.attribute` methods, a pointer to the updated network object.

list.network.attributes(g)
list.vertex.attributes(g)

#Note that we can do similar things using operators
g %n% "mygval" <- "boo" #Set attributes, as above
g %v% "myvval" <- letters[1:3]
g %e% "myeval" <- mm
g[,]% %names.eval="myeval"% <- mm #Another way to do this
g %n% "mygval" #Retrieve the attributes
g %v% "myvval"
g %e% "mevval"
as.sociomatrix(g,"myeval") # Or like this

---

deletion.methods  Remove Elements from a Network Object

Description

delete.edges removes one or more edges (specified by their internal ID numbers) from a network; delete.vertices performs the same task for vertices (removing all associated edges in the process).
Usage

```
delete.edges(x, eid)
delete.vertices(x, vid)
```

Arguments

- `x`: an object of class `network`.
- `eid`: a vector of edge IDs.
- `vid`: a vector of vertex IDs.

Details

Note that an edge’s ID number corresponds to its order within `x$mel`. To determine edge IDs, see `get.edgeIDs`. Likewise, vertex ID numbers reflect the order with which vertices are listed internally (e.g., the order of `x$oei` and `x$iel`, or that used by `as.matrix.network.adjacency`). When vertices are removed from a network, all edges having those vertices as endpoints are removed as well.

Edges can also be added/removed via the extraction/replacement operators. See the associated man page for details.

Value

Invisibly, a pointer to the updated network; these functions modify their arguments in place.

Author(s)

Carter T. Butts (buttsc@uci.edu)

g[1,2]<-0  # Remove an edge
g[,]  
g[,]<-0  # Remove all edges
g[,]  

edgeset.constructors

**Edgeset Constructors for Network Objects**

**Description**

These functions convert relational data in matrix form to network edge sets.

**Usage**

```r
network.adjacency(x, g, ignore.eval = TRUE, names.eval = NULL, ...)
network.edgelist(x, g, ignore.eval = TRUE, names.eval = NULL, ...)
network.incidence(x, g, ignore.eval = TRUE, names.eval = NULL, ...)
network.bipartite(x, g, ignore.eval = TRUE, names.eval = NULL, ...)
```

**Arguments**

- `x`: a matrix containing edge information
- `g`: an object of class `network`
- `ignore.eval`: logical; ignore edge values?
- `names.eval`: the edge attribute under which to store edge values, if any
- `...`: additional arguments to `add.edge`

**Details**

Each of the above functions takes a network and a matrix as input, and modifies the supplied network object by adding the appropriate edges. `network.adjacency` takes `x` to be an adjacency matrix; `code.edgelist` takes `x` to be an edgelist matrix; and `network.incidence` takes `x` to be an incidence matrix. `network.bipartite` takes `x` to be a two-mode adjacency matrix where rows and columns reflect each respective mode (conventionally, actors and events); if `ignore.eval` is `FALSE`, (non-zero) edge values are stored as edgewise attributes with name `names.eval`. Any additional command line parameters are passed to `add.edge`.

Results similar to `network.adjacency` can also be obtained by means of extraction/replacement operators. See the associated man page for details.

**Value**

Invisibly, an object of class `network`; these functions modify their argument in place.
Note
Handling of missing data is not yet fully implemented.

Data frame "emon"

Interorganizational Search and Rescue Networks (Drabek et al.)

Description
Drabek et al. (1981) provide seven case studies of emergent multi-organizational networks (EMONs) in the context of search and rescue (SAR) activities. Networks of interaction frequency are reported, along with several organizational attributes.

Usage
data(emon)
Format

A list of 7 network objects:

- [[1]] Cheyenne network Cheyenne SAR EMON
- [[2]] HurrFrederic network Hurricane Frederic SAR EMON
- [[3]] LakePomona network Lake Pomona SAR EMON
- [[4]] MtSi network Mt. Si SAR EMON
- [[5]] MtStHelens network Mt. St. Helens SAR EMON
- [[6]] Texas network Texas Hill Country SAR EMON
- [[7]] Wichita network Wichita Falls SAR EMON

Each network has one edge attribute:

Frequency numeric Interaction frequency (1-4; 1=most frequent)

Each network also has 8 vertex attributes:

- Command.Rank.Score numeric Mean rank in the command structure
- Decision.Rank.Score numeric Mean rank in the decision process
- Formalization numeric Degree of formalization
- Location character Location code
- Paid.Staff numeric Number of paid staff
- Sponsorship character Sponsorship type
- vertex.names character Organization name
- Volunteer.Staff numeric Number of volunteer staff

Details

All networks collected by Drabek et al. reflect reported frequency of organizational interaction during the search and rescue effort; the (i,j) edge constitutes i’s report regarding interaction with j, with non-adjacent vertices reporting no contact. Frequency is rated on a four-point scale, with 1 indicating the highest frequency of interaction. This is stored within the "Frequency" edge attribute.

For each network, several covariates are recorded as vertex attributes:

- **Command.Rank.Score** Mean (reversed) rank for the prominence of each organization in the command structure of the response, as judged by organizational informants.
- **Decision.Rank.Score** Mean (reversed) rank for the prominence of each organization in decision making processes during the response, as judged by organizational informants.
- **Formalization** An index of organizational formalization, ranging from 0 (least formalized) to 4 (most formalized).
- **Localization** For each organization, "L" if the organization was sited locally to the impact area, "NL" if the organization was not sited near the impact area, "B" if the organization was sited at both local and non-local locations.
- **Paid.Staff** Number of paid staff employed by each organization at the time of the response.
**Sponsorship** The level at which each organization was sponsored (e.g., "City", "County", "State", "Federal", and "Private").

**vertex.names** The identity of each organization.

**Volunteer.Staff** Number of volunteer staff employed by each organization at the time of the response.

Note that where intervals were given by the original source, midpoints have been substituted. For detailed information regarding data coding and procedures, see Drabek et al. (1981).

#A fancy display:
plot(nflo,displaylabels=TRUE,boxed.labels=FALSE,label.cex=0.75)

get.edges Retrieve Edges or Edge IDs Associated with a Given Vertex

Description

get.edges retrieves a list of edges incident on a given vertex; get.edgeIDs returns the internal identifiers for those edges, instead. Both allow edges to be selected based on vertex neighborhood and (optionally) an additional endpoint.

Usage

get.edges(x, v, alter = NULL, neighborhood = c("out", "in", "combined"), na.omit = TRUE)
get.edgeIDs(x, v, alter=NULL, neighborhood=c("out","in","combined"), na.omit=TRUE)

Arguments

x an object of class network
v a vertex ID
alter optionally, the ID of another vertex
neighborhood an indicator for whether we are interested in in-edges, out-edges, or both (relative to v)
na.omit logical; should we omit missing edges?

Details

By default, get.edges returns all out-, in-, or out- and in-edges containing v. (get.edgeIDs is identical, save in its return value.) Specifying a vertex in alter causes these edges to be further selected such that alter must also belong to the edge – this can be used to extract edges between two particular vertices. Omission of missing edges is accomplished via na.omit.
get.neighborhood

Value
For get.edges, a list of edges. For get.edgeIDs, a vector of edge ID numbers.

Author(s)
Carter T. Butts (buttsc@uci.edu)

References

See Also
get.neighborhood

Examples
# Create a network with three edges
m <- matrix(0, 3, 3)
m[1, 2] <- 1; m[2, 3] <- 1; m[3, 1] <- 1
x <- network(m)

get.edges(x, 1, neighborhood = "out")
get.edgeIDs(x, 1, neighborhood = "in")

get.neighborhood  Obtain the Neighborhood of a Given Vertex

Description
get.neighborhood returns the IDs of all vertices belonging to the in, out, or combined neighborhoods of v within network x.

Usage
get.neighborhood(x, v, type = c("out", "in", "combined"),
na.omit=TRUE)

Arguments
x an object of class network
v a vertex ID
type the neighborhood to be computed
na.omit logical; should missing edges be ignored when obtaining vertex neighborhoods?
Details

Note that the combined neighborhood is the union of the in and out neighborhoods – as such, no vertex will appear twice.

Value

A vector containing the vertex IDs for the chosen neighborhood.

Author(s)

Carter T. Butts (buttsc@uci.edu)

get.edges, is.adjacent

Examples

```r
# Create a network with three edges
m<-matrix(0,3,3)
m[1,2]<-1; m[2,3]<-1; m[3,1]<-1
g<-network(m)

# Examine the neighborhood of vertex 1
get.neighborhood(g,1,"out")
get.neighborhood(g,1,"in")
get.neighborhood(g,1,"combined")
```

---

**is.adjacent**  
*Determine Whether Two Vertices Are Adjacent*

**Description**

`is.adjacent` returns TRUE iff `vi` is adjacent to `vj` in `x`. Missing edges may be omitted or not, as per `na.omit`.

**Usage**

`is.adjacent(x, vi, vj, na.omit = TRUE)`
Arguments

x  an object of class network
vi a vertex ID
vj a second vertex ID
na.omit logical; should missing edges count when assessing adjacency?

Details

Vertex \( v \) is said to be adjacent to vertex \( v' \) within directed network \( G \) iff there exists some edge whose tail set contains \( v \) and whose head set contains \( v' \). In the undirected case, head and tail sets are exchangeable, and thus \( v \) is adjacent to \( v' \) if there exists an edge such that \( v \) belongs to one endpoint set and \( v' \) belongs to the other. (In dyadic graphs, these sets are of cardinality 1, but this may not be the case where hyperedges are admitted.)

Adjacency can also be determined via the extraction/replacement operators. See the associated man page for details.

Value

A logical, giving the status of the \((i,j)\) edge

network

Network Operators

Description

These operators allow for algebraic manipulation of relational structures.

Usage

"+.network"(x, y, attrname=NULL)
"-.network"(x, y, attrname=NULL)
"*.network"(x, y, attrname=NULL)
"%c%.network"(x, y)
"!.network"(x)
"|.network"(x, y)
"&.network"(x, y)

Arguments

x          an object of class network.
y          another network.
attrname   optionally, the name of an attribute to use for edge values.
Details

A more useful “usage” statement than the above (but prohibited by R’s overzealous documentation restrictions from appearing there) is as follows:

\[ x + y \]
\[ x - y \]
\[ x * y \]
\[ x \%c\% y \]

\[ !x \]
\[ x \mid y \]
\[ x \& y \]

\[ "+"(x, y, attrname=NULL) \]
\[ "-"(x, y, attrname=NULL) \]
\[ "*"(x, y, attrname=NULL) \]

In general, the binary network operators currently function by converting their arguments to adjacency matrices, carrying out the specified operation on those matrices, and then returning the result in network form. This is rather inefficient, and results in the loss of other attributes; such poor behavior is not guaranteed to be maintained in future versions of the \texttt{network} package.

Apart from the above, the specific operations carried out by these operators are mostly self-explanatory. One exception to this is \[ x \%c\% y \], which returns the network formed from the composition of graphs \[ x \] and \[ y \] (respectively). (Note that this may contain loops, whether or not the original networks allowed them.) Certain operators also support an \texttt{attrname} argument when called explicitly, which allows the user to specify an edge attribute to use when extracting the adjacency matrices. If such an argument is given, the resulting edge values are returned via an attribute of the same name in the newly constructed graph.

Slightly different behavior is exhibited by the unary operator, \[ ! \], which returns the complement of its argument. The graph which is returned contains all attributes of the original, save for edge attributes (as none of the original edges are retained). Note that the complement of a large, sparse graph has \textit{many} edges, with concomitant memory consumption. When working with such graphs, consider whether some other mechanism (e.g., adjacency checking on the original graph) might prove more efficient.

Value

The resulting graph object.

Note

Currently, there is a naming conflict between the composition operator and the \%c\% operator in the \texttt{sna} package. This will be resolved in future releases; for the time being, one can determine which version of \%c\% is in use by varying which package is loaded first.

**network-package**  
*Classes for Relational Data*

Description

Tools to create and modify network objects. The network class can represent a range of relational data types, and supports arbitrary vertex/edge/graph attributes.

Details

The `network` package provides tools for creation, access, and modification of network class objects. These objects allow for the representation of more complex structures than can be readily handled by other means (e.g., adjacency matrices), and are substantially more efficient in handling large, sparse networks. While the full capabilities of the `network` class can only be exploited by means of the various custom interface methods (see below), many simple tasks are streamlined through the use of operator overloading; in particular, network objects can often be treated as if they were adjacency matrices (a representation which will be familiar to users of the `sna` package). `network` objects are compatible with the `sna` package, and are required for many packages in the `statnet` bundle.
Basic information on the creation of network objects can be found by typing `help(network)`. To learn about setting, modifying, or deleting network, vertex, or edge attributes, see `help(attribute.methods)`. For information on custom network operators, type `help(network.operators)`; information on overloaded operators can be found via `help(network.extraction)`. Additional help topics are listed below.

which.matrix.type Heuristic Determination of Matrix Types for Network Storage

Author(s)
Carter T. Butts <buttsc@uci.edu>, with help from Mark S. Handcock <handcock@stat.washington.edu>, David Hunter <dhunter@stat.psu.edu> and Martina Morris <morrism@u.washington.edu>
Maintainer: Carter T. Butts <buttsc@uci.edu>

network Networks

Description
Construct, coerce to, test for and print network objects.

Usage
network(x, vertex.attr=NULL, vertex.attrnames=NULL, directed=TRUE, hyper=FALSE, loops=FALSE, multiple=FALSE, bipartite = FALSE, ...)
network.copy(x)
as.network(x, ...)
is.network(x)
print.network(x, matrix.type=which.matrix.type(x), mixingmatrices=FALSE, na.omit=TRUE, ...)
summary.network(object, na.omit=TRUE, mixingmatrices=FALSE, ...)

Arguments
x for network, a matrix giving the network structure in adjacency, incidence, or edgelist form; otherwise, an object of class network.
vertex.attr optionally, a list containing vertex attributes.
vertex.attrnames optionally, a list containing vertex attribute names.
directed logical; should edges be interpreted as directed?
hyper logical; are hyperedges allowed?
loops logical; should loops be allowed?
multiple logical; are multiplex edges allowed?
bipartite count; should the network be interpreted as bipartite? If present (i.e., non-NULL) it is the count of the number of actors in the bipartite network. In this case, the number of nodes is equal to the number of actors plus the number of events (with all actors preceeding all events). The edges are then interpreted as nondirected.
matrix.type one of "adjacency", "edgelist", "incidence".
object an object of class network.
network
na.omit logical; omit summarization of missing attributes in network?
mixingmatrices
network
... logical; print the mixing matrices for the discrete attributes?

Details

network constructs a network class object from a matrix representation.
network.copy creates a new network object which duplicates its supplied argument.

as.network tries to coerce its argument to a network, using the network function if necessary.
is.network tests whether its argument is a network (in the sense that it has class network).

print.network prints a network object in one of several possible formats. It also prints the list of global attributes of the network.

summary.network provides similar information.

Value

network, as.network, and print.network all return a network class object; is.network returns TRUE or FALSE.

Examples

m <- matrix(rbinom(25,1,.4),5,5)
diag(m) <- 0
g <- network(m, directed=FALSE)
summary(g)

h <- network.copy(g) #Note: h<-g will not have the same effect!
summary(h)
network.arrow  

Add Arrows or Segments to a Plot

Description

network.arrow draws a segment or arrow between two pairs of points; unlike arrows or segments, the new plot element is drawn as a polygon.

Usage

network.arrow(x0, y0, x1, y1, length = 0.1, angle = 20,  
width = 0.01, col = 1, border = 1, lty = 1, offset.head = 0,  
offset.tail = 0, arrowhead = TRUE, curve = 0, edge.steps = 50, ...)  

Arguments

- x0: A vector of x coordinates for points of origin  
- y0: A vector of y coordinates for points of origin  
- x1: A vector of x coordinates for destination points  
- y1: A vector of y coordinates for destination points  
- length: Arrowhead length, in current plotting units  
- angle: Arrowhead angle (in degrees)  
- width: Width for arrow body, in current plotting units (can be a vector)  
- col: Arrow body color (can be a vector)  
- border: Arrow border color (can be a vector)  
- lty: Arrow border line type (can be a vector)  
- offset.head: Offset for destination point (can be a vector)  
- offset.tail: Offset for origin point (can be a vector)  
- arrowhead: Boolean; should arrowheads be used? (Can be a vector)  
- curve: Degree of edge curvature (if any), in current plotting units (can be a vector)  
- edge.steps: For curved edges, the number of steps to use in approximating the curve (can be a vector)  
- ...: Additional arguments to polygon

Details

network.arrow provides a useful extension of segments and arrows when fine control is needed over the resulting display. (The results also look better.) Note that edge curvature is quadratic, with curve providing the maximum horizontal deviation of the edge (left-handed). Head/tail offsets are used to adjust the end/start points of an edge, relative to the baseline coordinates; these are useful for functions like plot.network, which need to draw edges incident to vertices of varying radii.
network.density

Value
None.

Note
network.arrow is a direct adaptation of gplot.arrow from the sna package.

Author(s)
Carter T. Butts ⟨buttsc@uci.edu⟩

See Also
plot.network, network.loop, polygon

Examples

#Plot two points
plot(1:2,1:2)

#Add an edge
network.arrow(1,1,2,2,width=0.01,col="red",border="black")

network.density  Compute the Density of a Network

Description
network.density computes the density of its argument.

Usage
network.density(x)

Arguments
x an object of class network

Details
The density of a network is defined as the ratio of extant edges to potential edges. We do not currently consider edge values; missing edges are automatically omitted.

Value
The network density.
network.dyadcount

Author(s)

Carter T. Butts (buttsc@uci.edu)

References

See Also

network.edgecount, network.size

Examples

#Create an arbitrary adjacency matrix
m<-matrix(rbinom(25,1,0.5),5,5)
diag(m)<-0
g<-network.initialize(5)  #Initialize the network
network.density(g)  #Calculate the density

Description

network.dyadcount returns the number of dyads within a network, removing those flagged as missing if desired.

Usage

network.dyadcount(x, na.omit = TRUE)

Arguments

x an object of class network
na.omit logical; omit edges with na==TRUE from the count?

Details

The return value network.dyadcount is equal to the number of dyads, minus the number of NULL edges (and missing edges, if na.omit==TRUE).

Value

The number of dyads in the network
network.edgecount

Return the Number of Edges in a Network Object

Description

network.edgecount returns the number of edges within a network, removing those flagged as missing if desired.

Usage

network.edgecount(x, na.omit = TRUE)

Arguments

x an object of class network
na.omit logical; omit edges with na==TRUE from the count?

Details

The return value network.edgecount is equal to x%n"mnext"-1, minus the number of NULL edges (and missing edges, if na.omit==TRUE). Note that g%n"mnext"-1 cannot, by itself, be counted upon to be an accurate count of the number of edges!

Value

The number of edges

network.edgecount(g) == 3  # Verify the edgecount

network.extraction  Extraction and Replacement Operators for Network Objects

Description

Various operators which allow extraction or replacement of various components of a network object.

Usage

## S3 method for class 'network':
x[i, j, na.omit = TRUE]
## S3 method for class 'network':
x[i, j, names.eval=NULL, add.edges=FALSE] <- value
x %e% attrname
x %e% attrname <- value
x %eattr% attrname
x %eattr% attrname <- value
x %n% attrname
x %n% attrname <- value
x %nattr% attrname
x %nattr% attrname <- value
x %v% attrname
x %v% attrname <- value
x %vattr% attrname
x %vattr% attrname <- value
network.extraction

Arguments

- **x**: an object of class `network`.
- **i, j**: indices of the vertices with respect to which adjacency is to be tested. Empty values indicate that all vertices should be employed (see below).
- **na.omit**: logical; should missing edges be omitted (treated as no-adjacency), or should NAs be returned?
- **names.eval**: optionally, the name of an edge attribute to use for assigning edge values.
- **add.edges**: logical; should new edges be added to `x` where edges are absent and the appropriate element of `value` is non-zero?
- **value**: the value (or set thereof) to be assigned to the selected element of `x`.
- **attrname**: the name of a network or vertex attribute (as appropriate).

Details

Indexing for edge extraction operates in a manner analogous to matrix objects. Thus, `x[,]` selects all vertex pairs, `x[1,-5]` selects the pairing of vertex 1 with all vertices except for 5, etc. Following this, it is acceptable for `i` and/or `j` to be logical vectors indicating which vertices are to be included. During assignment, an attempt is made to match the elements of `value` to the extracted pairs in an intelligent way; in particular, elements of `value` will be replicated if too few are supplied (allowing expressions like `x[,]<-1`). Where `names.eval==NULL`, zero and non-zero values are taken to indicate the presence of absence of edges. `x[2,4]<-6` thus adds a single (2,4) edge to `x`, and `x[2,4]<-0` removes such an edge (if present). If `x` is multiplex, assigning 0 to a vertex pair will eliminate all edges on that pair. Pairs are taken to be directed where `is.directed(x)==TRUE`, and undirected where `is.directed(x)==FALSE`.

If an edge attribute is specified using `names.eval`, then the provided values will be assigned to that attribute. When assigning values, only extant edges are employed (unless `add.edges==TRUE`); in the latter case, any non-zero assignment results in the addition of an edge where currently absent. If the attribute specified is not present on a given edge, it is added. Otherwise, any existing value is overwritten. The `%e%` operator can also be used to extract/assign edge values; in those roles, it is respectively equivalent to `get.edge.value(x,attrname)` and `set.edge.value(x,attrname=attrname,value=value)`.

The `%n%` and `%v%` operators serve as front-ends to the network and vertex extraction/assignment functions (respectively). In the extraction case, `x %n% attrname` is equivalent to `get.network.attribute(x,attrname)` with `x %v% attrname` corresponding to `get.vertex.attribute(x,attrname)`. In assignment, the respective equivalences are to `set.network.attribute(x,attrname,value)` and `set.vertex.attribute(x,attrname,value)`.

The `%eattr%`, `%nattr%`, and `%vattr%` operators are equivalent to `%e%`, `%n%`, and `%v%` (respectively). The short forms are more succinct, but may produce less readable code.

Value

The extracted data, or none.

network.indicators  Indicator Functions for Network Properties

Description

Various indicators for properties of network class objects.

Usage

has.loops(x)
is.bipartite(x)
is.directed(x)
is.hyper(x)
is.multiplex(x)

Arguments

x  an object of class network
Details

These methods are the standard means of assessing the state of a network object; other methods can (and should) use these routines in governing their own behavior. As such, improper setting of the associated attributes may result in unpleasantly creative results. (See the edge.check argument to add.edges for an example of code which makes use of these network properties.)

The functions themselves behave as follows:

has.loops returns TRUE iff x is allowed to contain loops (or loop-like edges, in the hypergraphic case).

is.bipartite returns TRUE iff the x has been explicitly bipartite-coded. (Note that is.bipartite refers only to the storage properties of x; is.bipartite(x)==FALSE it does not mean that x cannot admit a bipartition!)

is.directed returns TRUE iff the edges of x are to be interpreted as directed.

is.hyper returns TRUE iff x is allowed to contain hypergraphic edges.

is.multiplex returns TRUE iff x is allowed to contain multiplex edges.

Value

TRUE or FALSE

Author(s)

Carter T. Butts (buttsc@uci.edu)

Examples

g<-network.initialize(5)       #Initialize the network
is.bipartite(g)
is.directed(g)
is.hyper(g)
is.multiplex(g)
has.loops(g)
Initialize a Network Class Object

Description

Create and initialize a network object with \( n \) vertices.

Usage

```r
network.initialize(n, directed = TRUE, hyper = FALSE, loops = FALSE,
                   multiple = FALSE, bipartite = FALSE)
```

Arguments

- `n`: the number of vertices to initialize
- `directed`: logical; should edges be interpreted as directed?
- `hyper`: logical; are hyperedges allowed?
- `loops`: logical; should loops be allowed?
- `multiple`: logical; are multiplex edges allowed?
- `bipartite`: count; should the network be interpreted as bipartite? If present (i.e., non-NULL) it is the count of the number of actors in the bipartite network. In this case, the number of nodes is equal to the number of actors plus the number of events (with all actors preceding all events). The edges are then interpreted as nondirected.

Details

Generally, `network.initialize` is called by other constructor functions as part of the process of creating a network.

Value

An object of class `network`

Author(s)

Carter T. Butts (butts@uci.edu)

References

**Examples**

```r
g <- network.initialize(5) # Create an empty graph on 5 vertices
```

---

**network.layout**

*Vertex Layout Functions for plot.network*

**Description**

Various functions which generate vertex layouts for the `plot.network` visualization routine.

**Usage**

```r
network.layout.circle(d, layout.par)
network.layout.fruchtermanreingold(d, layout.par)
network.layout.kamadakawai(d, layout.par)
```

**Arguments**

- `d`: an adjacency matrix, as passed by `plot.network`.
- `layout.par`: a list of parameters.

**Details**

Vertex layouts for network visualization pose a difficult problem – there is no single, “good” layout algorithm, and many different approaches may be valuable under different circumstances. With this in mind, `plot.network` allows for the use of arbitrary vertex layout algorithms via the `network.layout.*` family of routines. When called, `plot.network` searches for a `network.layout.function` whose fourth name matches its `mode` argument (see `plot.network` help for more information); this function is then used to generate the layout for the resulting plot. In addition to the routines documented here, users may add their own layout functions as needed.

The requirements for a `network.layout.function` are as follows:

1. the first argument, `d`, must be the (dichotomous) graph adjacency matrix;
2. the second argument, `layout.par`, must be a list of parameters (or `NULL`, if no parameters are specified); and
3. the return value must be a real matrix of dimension `c(2, NROW(d))`, whose rows contain the vertex coordinates.

Other than this, anything goes. (In particular, note that `layout.par` could be used to pass additional matrices, if needed.)

The `network.layout` functions currently supplied by default are as follows:

- **circle** This function places vertices uniformly in a circle; it takes no arguments.
- **fruchtermanreingold** This function generates a layout using a variant of Fruchterman and Reingold’s force-directed placement algorithm. It takes the following arguments:
layout.par$niter This argument controls the number of iterations to be employed. (Defaults to 500.)

layout.par$max.delta Sets the maximum change in position for any given iteration. (Defaults to NROW(d).)

layout.par$area Sets the "area" parameter for the F-R algorithm. (Defaults to NROW(d) ^2.)

layout.par$cool.exp Sets the cooling exponent for the annealer. (Defaults to 3.)

layout.par$repulse.rad Determines the radius at which vertex-vertex repulsion cancels out attraction of adjacent vertices. (Defaults to area*NROW(d).)

layout.par$seed.coord A two-column matrix of initial vertex coordinates. (Defaults to a random circular layout.)

kamadakawai This function generates a vertex layout using a version of the Kamada-Kawai force-directed placement algorithm. It takes the following arguments:

layout.par$niter This argument controls the number of iterations to be employed. (Defaults to 1000.)

layout.par$sigma Sets the base standard deviation of position change proposals. (Defaults to NROW(d) / 4.)

layout.par$initemp Sets the initial "temperature" for the annealing algorithm. (Defaults to 10.)

layout.par$cool.exp Sets the cooling exponent for the annealer. (Defaults to 0.99.)

layout.par$kkconst Sets the Kamada-Kawai vertex attraction constant. (Defaults to NROW(d) ^2.)

layout.par$elen Provides the matrix of interpoint distances to be approximated. (Defaults to the geodesic distances of d after symmetrizing, capped at sqrt(NROW(d)).)

layout.par$seed.coord A two-column matrix of initial vertex coordinates. (Defaults to a gaussian layout.)

Value

A matrix whose rows contain the x,y coordinates of the vertices of d.

Note

The network.layout routines shown here are adapted directly from the gplot.layout routines of the sna package.

Author(s)

Carter T. Butts (buttsc@uci.edu)

References

plot.network
network.loop  

Add Loops to a Plot

Description

network.loop draws a "loop" at a specified location; this is used to designate self-ties in plot.network.

Usage

network.loop(x0, y0, length = 0.1, angle = 10, width = 0.01, col = 1, border = 1, lty = 1, offset = 0, edge.steps = 10, radius = 1, arrowhead = TRUE, xctr=0, yctr=0, ...)

Arguments

x0  

a vector of x coordinates for points of origin.

y0  

a vector of y coordinates for points of origin.

length  

arrowhead length, in current plotting units.

angle  

arrowhead angle (in degrees).

width  

width for loop body, in current plotting units (can be a vector).

col  

loop body color (can be a vector).

border  

loop border color (can be a vector).

lty  

loop border line type (can be a vector).

offset  

offset for origin point (can be a vector).

edge.steps  

number of steps to use in approximating curves.

radius  

loop radius (can be a vector).

arrowhead  

boolean; should arrowheads be used? (Can be a vector.)

xctr  

x coordinate for the central location away from which loops should be oriented.

yctr  

y coordinate for the central location away from which loops should be oriented.

...  

additional arguments to polygon.

Details

network.loop is the companion to network.arrow; like the latter, plot elements produced by network.loop are drawn using polygon, and as such are scaled based on the current plotting device. By default, loops are drawn so as to encompass a circular region of radius radius, whose center is offset units from x0,y0 and at maximum distance from xctr,yctr. This is useful for functions like plot.network, which need to draw loops incident to vertices of varying radii.

Value

None.
network.size

Description

network.size returns the order of its argument (i.e., number of vertices).

Usage

network.size(x)

Arguments

x an object of class network

Details

network.size(x) is equivalent to get.network.attribute(x, "n"); the function exists as a convenience.

Value

The network size

Author(s)

Carter T. Butts (butts@uci.edu)
network.vertex

References

get.network.attribute

Examples

#Initialize a network
g<-network.initialize(7)
network.size(g)

---

**network.vertex**  *Add Vertices to a Plot*

Description

*network.vertex* adds one or more vertices (drawn using polygon) to a plot.

Usage

```r
network.vertex(x, y, radius = 1, sides = 4, border = 1, col = 2,
                lty = NULL, rot = 0, ...)
```

Arguments

- `x`  
a vector of x coordinates.
- `y`  
a vector of y coordinates.
- `radius`  
a vector of vertex radii.
- `sides`  
a vector containing the number of sides to draw for each vertex.
- `border`  
a vector of vertex border colors.
- `col`  
a vector of vertex interior colors.
- `lty`  
a vector of vertex border line types.
- `rot`  
a vector of vertex rotation angles (in degrees).
- `...`  
Additional arguments to *polygon*

Details

*network.vertex* draws regular polygons of specified radius and number of sides, at the given coordinates. This is useful for routines such as *plot.network*, which use such shapes to depict vertices.
permute.vertexIDs

Value

None

Note

network.vertex is a direct adaptation of gplot.vertex from the sna package.

Author(s)

Carter T. Butts ⟨buttsc@uci.edu⟩

See Also

plot.network, polygon

Examples

#Open a plot window, and place some vertices
plot(0,0,type="n",xlim=c(-1.5,1.5),ylim=c(-1.5,1.5),asp=1)
network.vertex(cos((1:10)/10*2*pi),sin((1:10)/10*2*pi),col=1:10,
sides=3:12,radius=0.1)

permute.vertexIDs  Permute (Relabel) the Vertices Within a Network

Description

permute.vertexIDs permutes the vertices within a given network in the specified fashion. Since this occurs internally (at the level of vertex IDs), it is rarely of interest to end-users.

Usage

permute.vertexIDs(x, vids)

Arguments

x an object of class network.
vids a vector of vertex IDs, in the order to which they are to be permuted.

Details

permute.vertexIDs alters the internal ordering of vertices within a network. For most practical applications, this should not be necessary – de facto permutation can be accomplished by altering the appropriate vertex attributes. permute.vertexIDs is needed for certain other routines (such as delete.vertices), where it is used in various arcane and ineffable ways.
Value

Invisibly, a pointer to the permuted network. permute.vertexIDs modifies its argument in place.

Two-Dimensional Visualization for Network Objects

Description

plot.network produces a simple two-dimensional plot of network x, using optional attribute attrname to set edge values. A variety of options are available to control vertex placement, display details, color, etc.

Usage

plot.network(x, ...)

plot.network.default(x, attrname = NULL,
    label = network.vertex.names(x), coord = NULL, jitter = TRUE,
    thresh = 0, usearrows = TRUE, mode = "fruchtermanreingold",
    displayisolates = TRUE, interactive = FALSE, xlab = NULL,
    ylab = NULL, xlim = NULL, ylim = NULL, pad = 0.2, label.pad = 0.5,
    displaylabels = FALSE, boxed.labels = TRUE, label.pos = 0,
    label.bg = "white", vertex.sides = 8, vertex.rot = 0,
    arrowhead.cex = 1, label.cex = 1, loop.cex = 1, vertex.cex = 1,
    edge.col = 1, label.col = 1, vertex.col = 2, label.border = 1,
vertex.border = 1, edge.lty = 1, label.lty = NULL, vertex.lty = 1, edge.lwd = 0, label.lwd = par("lwd"), edge.len = 0.5, edge.curve = 0.1, edge.steps = 50, loop.steps = 20, object.scale = 0.01, use.len = FALSE, use.curve = FALSE, suppress.axes = TRUE, vertices.last = TRUE, new = TRUE, layout.par = NULL, ...)

Arguments

x an object of class network.
attrname an optional edge attribute, to be used to set edge values.
label a vector of vertex labels, if desired; defaults to the vertex labels returned by network.vertex.names.
coord user-specified vertex coordinates, in an NCOL(dat)x2 matrix. Where this is specified, it will override the mode setting.
jitter boolean; should the output be jittered?
thresh real number indicating the lower threshold for tie values. Only ties of value >thresh are displayed. By default, thresh=0.
usearrows boolean; should arrows (rather than line segments) be used to indicate edges?
mode the vertex placement algorithm; this must correspond to a network.layout function.
displayisolates boolean; should isolates be displayed?
interactive boolean; should interactive adjustment of vertex placement be attempted?
xlab x axis label.
ylab y axis label.
xlim the x limits (min, max) of the plot.
ylim the y limits of the plot.
pad amount to pad the plotting range; useful if labels are being clipped.
label.pad amount to pad label boxes (if boxed.labels==TRUE), in character size units.
displaylabels boolean; should vertex labels be displayed?
boxed.labels boolean; place vertex labels within boxes?
label.pos position at which labels should be placed, relative to vertices. 0 results in labels which are placed away from the center of the plotting region; 1, 2, 3, and 4 result in labels being placed below, to the left of, above, and to the right of vertices (respectively); and label.pos>=5 results in labels which are plotted with no offset (i.e., at the vertex positions).
label.bg background color for label boxes (if boxed.labels==TRUE); may be a vector, if boxes are to be of different colors.
vertex.sides number of polygon sides for vertices; may be given as a vector or a vertex attribute name, if vertices are to be of different types.
vertex.rot  angle of rotation for vertices (in degrees); may be given as a vector or a vertex attribute name, if vertices are to be rotated differently.

arrowhead.cex  expansion factor for edge arrowheads.

label.cex  character expansion factor for label text.

loop.cex  expansion factor for loops; may be given as a vector or a vertex attribute name, if loops are to be of different sizes.

vertex.cex  expansion factor for vertices; may be given as a vector or a vertex attribute name, if vertices are to be of different sizes.

edge.col  color for edges; may be given as a vector, adjacency matrix, or edge attribute name, if edges are to be of different colors.

label.col  color for vertex labels; may be given as a vector or a vertex attribute name, if labels are to be of different colors.

vertex.col  color for vertices; may be given as a vector or a vertex attribute name, if vertices are to be of different colors.

label.border  label border colors (if boxed.labels==TRUE); may be given as a vector, if label boxes are to have different colors.

vertex.border  border color for vertices; may be given as a vector or a vertex attribute name, if vertex borders are to be of different colors.

edge.lty  line type for edge borders; may be given as a vector, adjacency matrix, or edge attribute name, if edge borders are to have different line types.

label.lty  line type for label boxes (if boxed.labels==TRUE); may be given as a vector, if label boxes are to have different line types.

vertex.lty  line type for vertex borders; may be given as a vector or a vertex attribute name, if vertex borders are to have different line types.

edge.lwd  line width scale for edges; if set greater than 0, edge widths are scaled by edge.lwd*dat. May be given as a vector, adjacency matrix, or edge attribute name, if edges are to have different line widths.

label.lwd  line width for label boxes (if boxed.labels==TRUE); may be given as a vector, if label boxes are to have different line widths.

edge.len  if uselen==TRUE, curved edge lengths are scaled by edge.len.

edge.curve  if usecurve==TRUE, the extent of edge curvature is controlled by edge.curv. May be given as a fixed value, vector, adjacency matrix, or edge attribute name, if edges are to have different levels of curvature.

edge.steps  for curved edges (excluding loops), the number of line segments to use for the curve approximation.

loop.steps  for loops, the number of line segments to use for the curve approximation.

object.scale  base length for plotting objects, as a fraction of the linear scale of the plotting region. Defaults to 0.01.

uselen  boolean; should we use edge.len to rescale edge lengths?

usecurve  boolean; should we use edge.curve?
plot.network.default

**supress.axes**
- boolean; suppress plotting of axes?

**vertices.last**
- boolean; plot vertices after plotting edges?

**new**
- boolean; create a new plot? If new==FALSE, vertices and edges will be added to the existing plot.

**layout.par**
- parameters to the network.layout function specified in mode.

... additional arguments to plot.

**Details**

plot.network is the standard visualization tool for the network class. By means of clever selection of display parameters, a fair amount of display flexibility can be obtained. Vertex layout – if not specified directly using coord – is determined via one of the various available algorithms. These should be specified via the mode argument; see network.layout for a full list. User-supplied layout functions are also possible – see the aforementioned man page for details.

Note that where is.hyper(x)==TRUE, the network is converted to bipartite adjacency form prior to computing coordinates. If interactive==TRUE, then the user may modify the initial network layout by selecting an individual vertex and then clicking on the location to which this vertex is to be moved; this process may be repeated until the layout is satisfactory.

**Value**

A two-column matrix containing the vertex positions as x,y coordinates

**Note**

plot.network is adapted (with minor modifications) from the gplot function of the sna library (authors: Carter T. Butts and Alex Montgomery); eventually, these two packages will be integrated.

**Author(s)**

Carter T. Butts (butsc@uci.edu)

Examples

# Construct a sparse graph
m<-matrix(rbinom(100,1,1.5/9),10)
diag(m)<-0
g<-network(m)

# Plot the graph
plot(g)

# Load Padgett's marriage data
data(flo)
nflo<-network(flo)
# Display the network, indicating degree and flagging the Medicis
plot(nflo, vertex.cex=apply(flo,2,sum)+1, usearrows=FALSE,
     vertex.sides=3+apply(flo,2,sum),
     vertex.col=2+(network.vertex.names(nflo)=="Medici"))

---

read.paj

Read a Pajek Project or Network File and Convert to an R ‘Network’ Object

Description

Return a (list of) network object(s) after reading a corresponding .net or .paj file. The code accepts ragged array edgelists, but cannot currently handle 2-mode, multirelational (e.g. KEDS), or networks with entries for both edges and arcs (e.g. GD-a99m). Also, this archive currently only contains networks under 10,000 nodes. See network, statnet, or sna for more information.

Usage

read.paj(file, verbose = FALSE, debug = FALSE, edge.name = NULL, simplify = FALSE)

Arguments

file the name of the file whence the data are to be read. If it does not contain an absolute path, the file name is relative to the current working directory (as returned by getwd). file can also be a complete URL.

verbose logical: Should longer descriptions of the reading and coercion process be printed out?

debug logical: Should very detailed descriptions of the reading and coercion process be printed out? This is typically used to debug the reading of files that are corrupted on coercion.

edge.name optional name for the edge variable read from the file. The default is to use the value in the project file.
which.matrix.type

simplify

Should the returned network be simplified as much as possible and saved? The values specifies the name of the file which the data are to be stored. If it does not contain an absolute path, the file name is relative to the current working directory (see getwd). If specify is TRUE the file name is the name file.

Value

read.paj returns a ‘network’ object (for .net input) or a list of networks (for .paj input). Additional information in the .paj file (like partition information) is attached to the network objects in another higher order list.

Examples

## Not run:
require(network)
par(mfrow=c(2,2))
test.net.1 <- read.paj("http://vlado.fmf.uni-lj.si/pub/networks/data/GD/gd98/A98.net")
plot(test.net.1,main=test.net.1$gal$title)
test.net.2 <- read.paj("http://vlado.fmf.uni-lj.si/pub/networks/data/mix/USAir97.net")
plot(test.net.2,main=test.net.2$gal$title)
## End(Not run)
Details

The heuristics used to determine matrix types are fairly arbitrary, and should be avoided where possible. This function is intended to provide a modestly intelligent fallback option when explicit identification by the user is not possible.

Value

One of "adjacency", "incidence", or "edgelist"
